

**Lecture 8:**

# **Geometric Queries**

---

**Interactive Computer Graphics  
Stanford CS248, Winter 2021**

# Geometric queries — motivation

**Intersecting rays and triangles  
(ray tracing)**

**Intersecting triangles (collisions)**

**Closest point on surface queries**

# Example: closest point queries

- **Q: Given a point, in space (e.g., a new sample point), how do we find the closest point on a given surface?**
- **Q: Does implicit/explicit representation make this easier?**
- **Q: Does our half-edge data structure help?**
- **Q: What's the cost of the naïve algorithm?**
- **Q: How do we find the distance to a single triangle anyway?**

# Many types of geometric queries

- **Plenty of other things we might like to know:**

- **Do two triangles intersect?**
- **Are we inside or outside an object?**
- **Does one object contain another?**
- ...

- **Data structures we've seen so far not really designed for this...**

- **Need some new ideas!**

- **TODAY: come up with simple (aka: slow) algorithms**

- **NEXT TIME: intelligent ways to accelerate geometric queries**

# Warm up: closest point on point

Given a query point  $(p_x, p_y)$ , how do we find the closest point on the point  $(a_x, a_y)$ ?

**Bonus question: what's the distance?**

# Slightly harder: closest point on line

- Now suppose I have a line  $N^T x = c$ , where  $N$  is the unit normal
  - Remember: a line is all points  $x$  such that  $N^T x = c$
- How do I find the point on the line closest to my query point  $p$ ?

# Review: matrix form of a line (and a plane)

Line is defined by:

- Its normal:  $\mathbf{N}$
- A point  $\mathbf{x}_0$  on the line

$$\mathbf{N} \cdot (\mathbf{x} - \mathbf{x}_0) = 0$$

$$\mathbf{N}^T (\mathbf{x} - \mathbf{x}_0) = 0$$

$$\mathbf{N}^T \mathbf{x} = \mathbf{N}^T \mathbf{x}_0$$

$$\mathbf{N}^T \mathbf{x} = c$$

**The line (in 2D) is all points  $\mathbf{x}$ , where  $\mathbf{x} - \mathbf{x}_0$  is orthogonal to  $\mathbf{N}$ .**  
( $\mathbf{N}, \mathbf{x}, \mathbf{x}_0$  are 2-vectors)

**(And a plane (in 3D) is all points  $\mathbf{x}$  where  $\mathbf{x} - \mathbf{x}_0$  is orthogonal to  $\mathbf{N}$ .)**

( $\mathbf{N}, \mathbf{x}, \mathbf{x}_0$  are 3-vectors)

# Closest point on line

- Now suppose I have a line  $\mathbf{N}^T \mathbf{x} = c$ , where  $\mathbf{N}$  is the unit normal
  - Remember: a line is all points  $\mathbf{x}$  such that  $\mathbf{N}^T \mathbf{x} = c$
- How do I find the point on line closest to my query point  $\mathbf{p}$ ?

Many ways to do it:  $\mathbf{N}^T (\mathbf{p} + t\mathbf{N}) = c$

$$\iff \mathbf{N}^T \mathbf{p} + t\mathbf{N}^T \mathbf{N} = c$$

$$\iff t = c - \mathbf{N}^T \mathbf{p}$$

$$\Rightarrow \mathbf{p} + t\mathbf{N} = \boxed{\mathbf{p} + (c - \mathbf{N}^T \mathbf{p})\mathbf{N}}$$

# Harder: closest point on line segment

- **Two cases: endpoint or interior**
- **Already have basic components:**
  - **point-to-point**
  - **point-to-line**
- **Algorithm?**
  - **find closest point on line**
  - **check if it is between endpoints**
  - **if not, take closest endpoint**
- **How do we know if it's between endpoints?**
  - **write closest point on line as  $a+t(b-a)$**
  - **if  $t$  is between 0 and 1, it's inside the segment!**

# Even harder: closest point on triangle in 2D

- What are all the possibilities for the closest point?
- Almost just minimum distance to three line segments:

**Q: What about a point inside the triangle?**

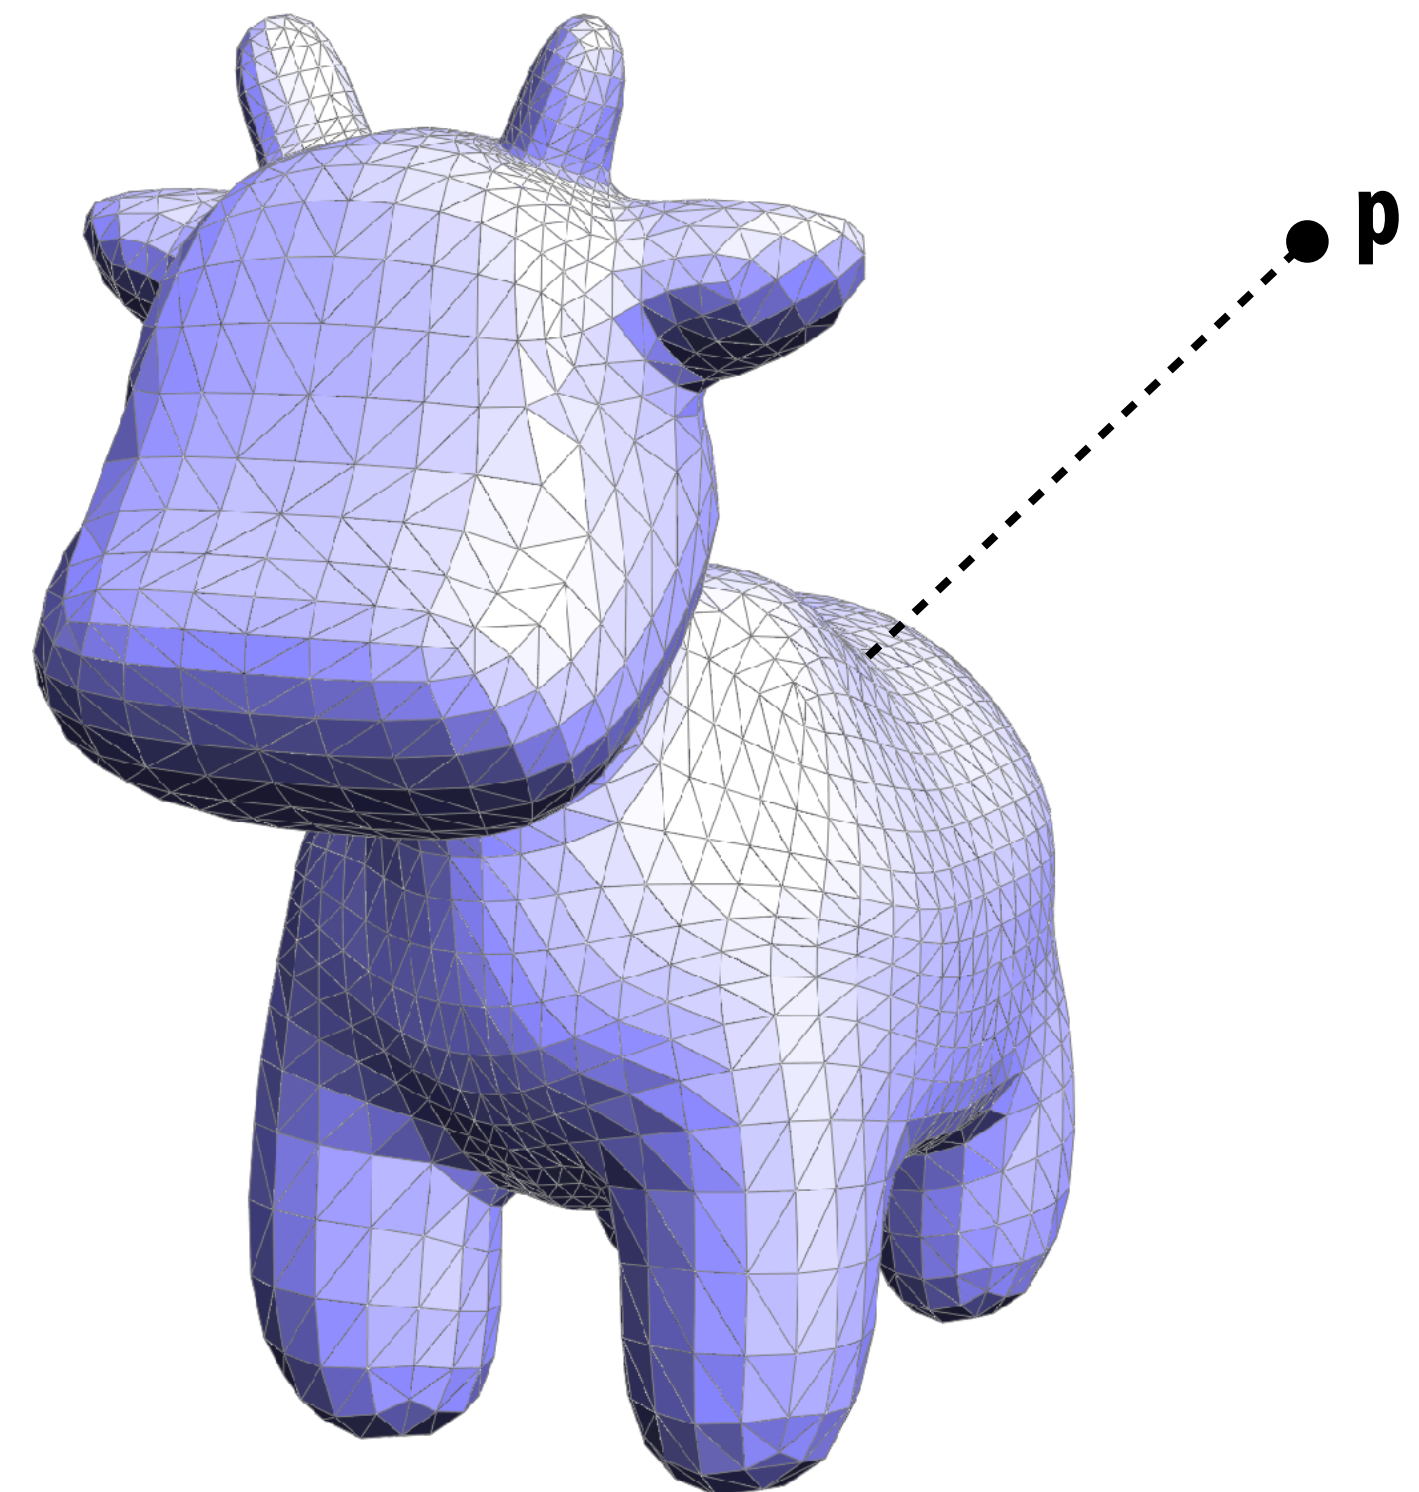

# Closest point on triangle in 3D

- Not so different from 2D case
- Algorithm:
  - Project point onto plane of triangle
  - Use three *half-plane* tests to classify point (vs. half plane)
  - If inside the triangle, we're done!
  - Otherwise, find closest point on associated vertex or edge
- By the way, how do we find closest point on plane?
- Same expression as closest point on a line!  $p + (c - N^T p) N$

# Closest point on triangle *mesh* in 3D?

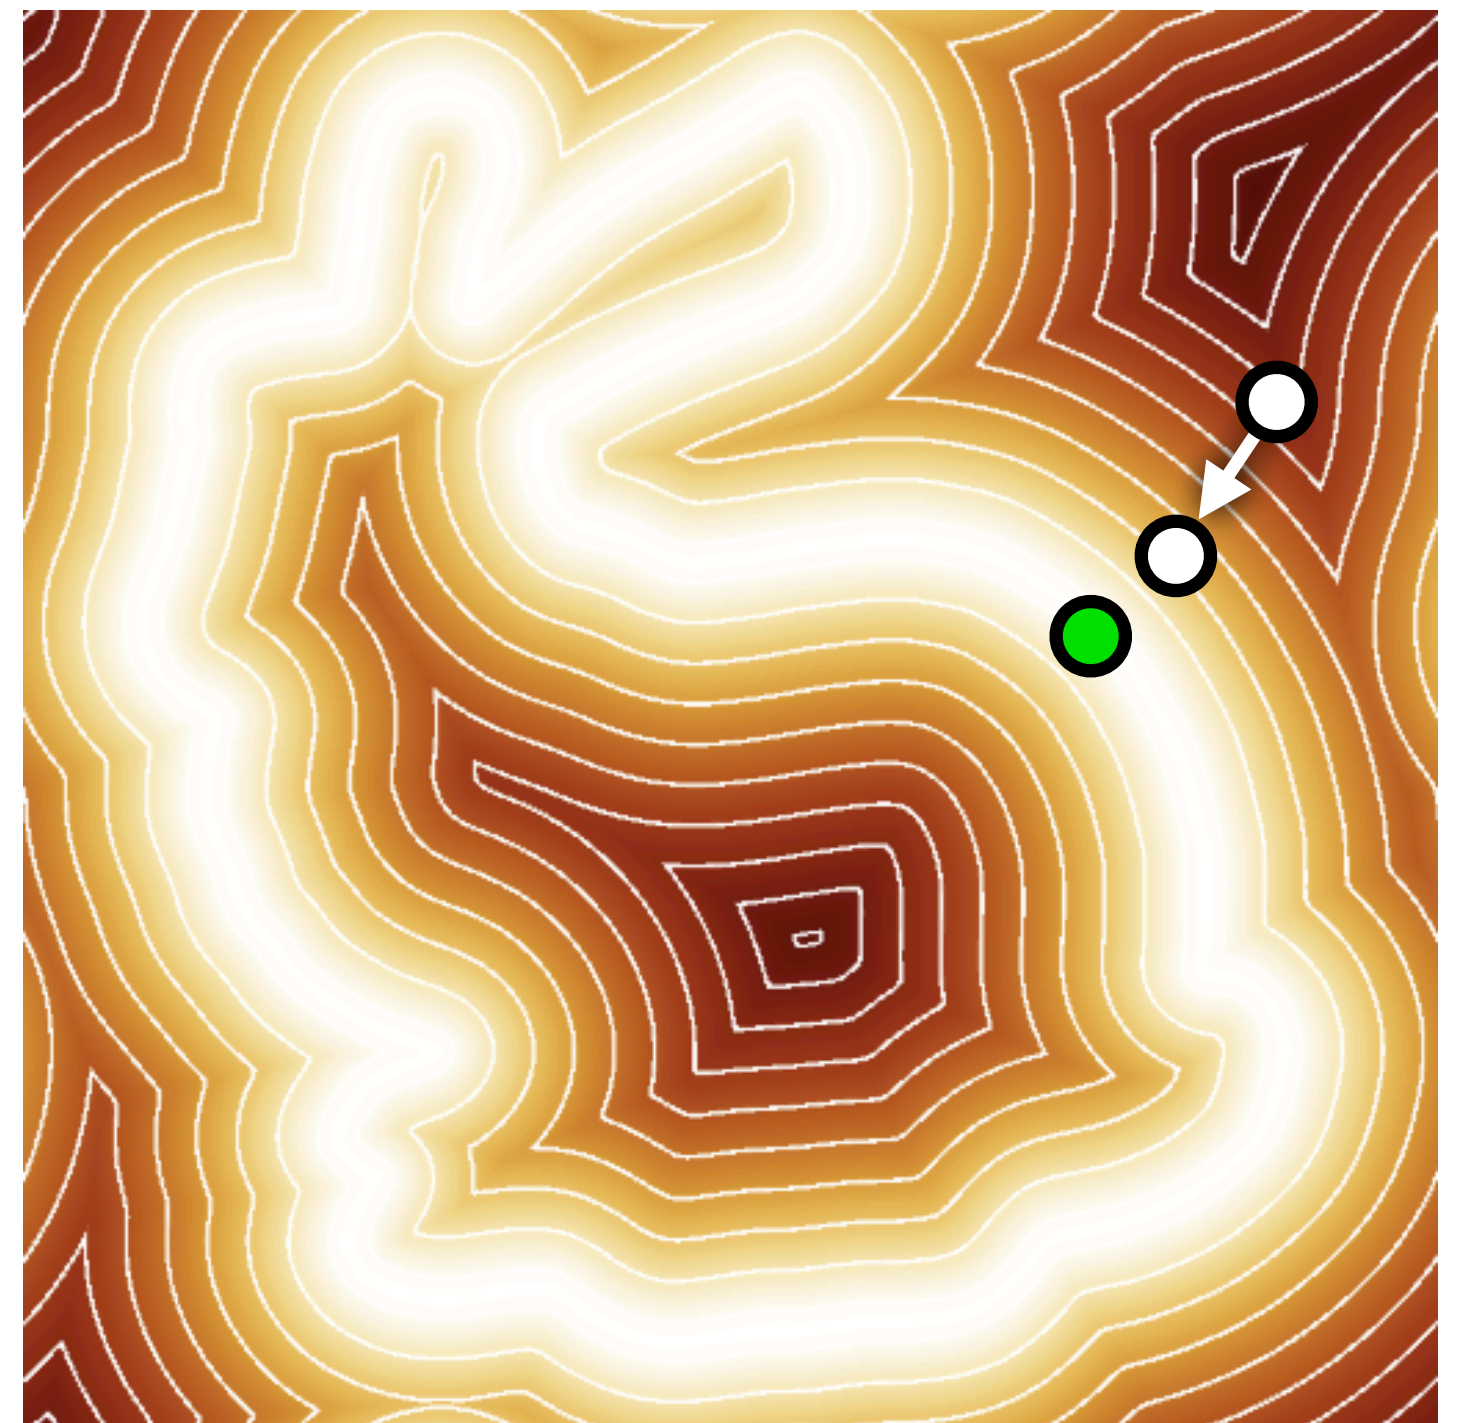

- **Conceptually easy:**
  - loop over all triangles
  - compute closest point to current triangle
  - keep globally closest point
- **Q: What's the cost?**
- **What if we have *billions* of faces?**
- **NEXT TIME: Better data structures!**

# Closest point to *implicit* surface?

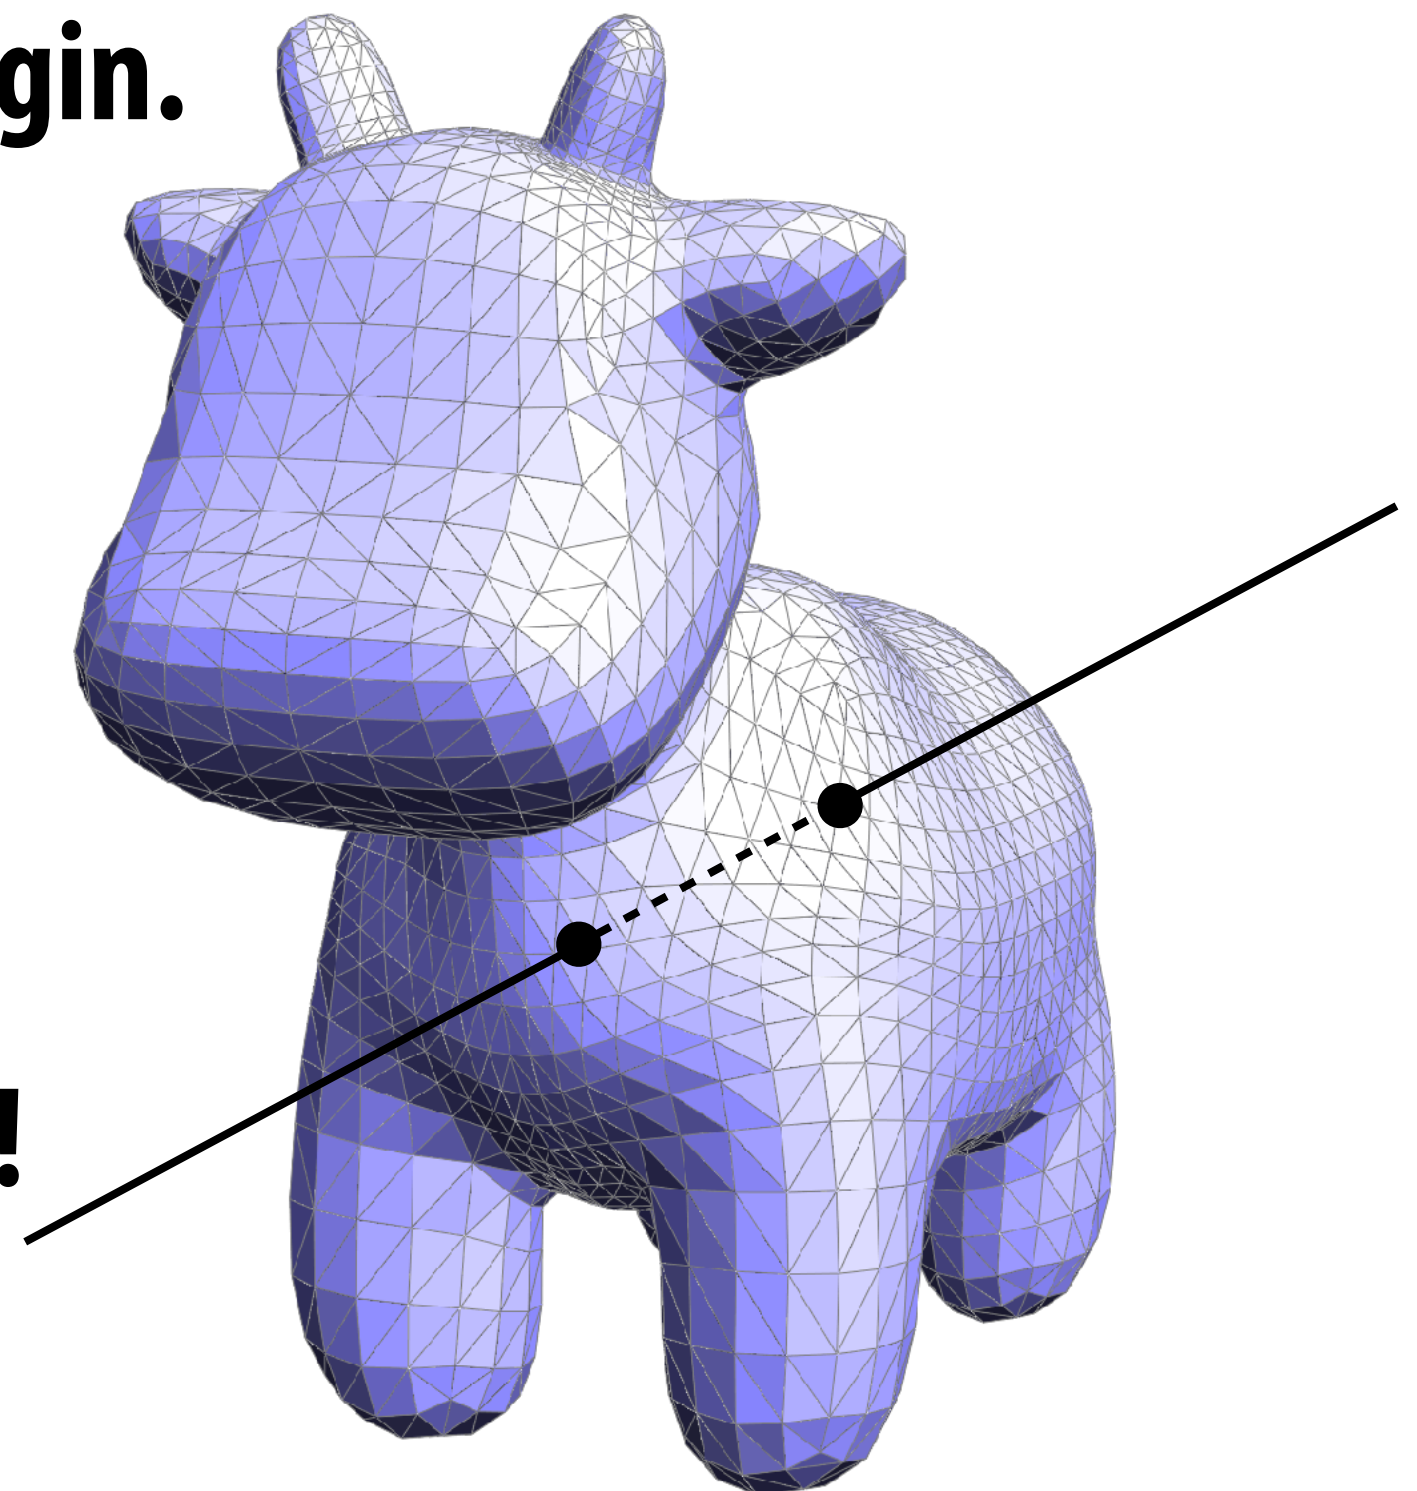

- If we change our representation of geometry, algorithms can change completely
- E.g., how might we compute the closest point on an implicit surface described via its distance function?
- One idea:
  - start at the query point
  - compute gradient of distance (using, e.g., finite differences)
  - take a little step (decrease distance)
  - repeat until we're at the surface (zero distance)
- Better yet: just store closest point for each grid cell! (speed/memory trade off)

# Different query: ray-mesh intersection

- A “ray” is an oriented line starting at a point
- Think about a ray of light traveling from the sun
- Want to know where a ray pierces a surface
  - Notice: this is a different query than finding the closest point on surface from ray’s origin.
- Applications?
  - GEOMETRY: inside-outside test
  - RENDERING: visibility, ray tracing
  - ANIMATION: collision detection
- Ray might pierce surface in many places!

# Ray equation

- Can express ray as

# Intersecting a ray with an implicit surface

- Recall implicit surfaces: all points  $\mathbf{x}$  such that  $f(\mathbf{x}) = 0$
- Q: How do we find points where a ray pierces this surface?
- Well, we know all points along the ray:  $\mathbf{r}(t) = \mathbf{o} + t\mathbf{d}$
- Idea: replace “ $\mathbf{x}$ ” with “ $\mathbf{r}$ ” in 1st equation, and solve for  $t$
- Example: unit sphere

$$f(\mathbf{x}) = |\mathbf{x}|^2 - 1$$

$$\Rightarrow f(\mathbf{r}(t)) = |\mathbf{o} + t\mathbf{d}|^2 - 1$$

$$\underbrace{|\mathbf{d}|^2}_{a} t^2 + \underbrace{2(\mathbf{o} \cdot \mathbf{d})}_{b} t + \underbrace{|\mathbf{o}|^2 - 1}_{c} = 0$$

Note:  $|\mathbf{d}|^2 = 1$  since  $\mathbf{d}$  is a unit vector

$$t = \boxed{-\mathbf{o} \cdot \mathbf{d} \pm \sqrt{(\mathbf{o} \cdot \mathbf{d})^2 - |\mathbf{o}|^2 + 1}}$$

quadratic formula:

$$t = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

Why two solutions?

# Ray-plane intersection

- Suppose we have a plane  $\mathbf{N}^T \mathbf{x} = c$

- $\mathbf{N}$  - unit normal
- $c$  - offset

- How do we find intersection with ray  $\mathbf{r}(t) = \mathbf{o} + t\mathbf{d}$ ?

- *Key idea:* again, replace the point  $\mathbf{x}$  with the ray equation  $t$ :

$$\mathbf{N}^T \mathbf{r}(t) = c$$

- Now solve for  $t$ :

$$\mathbf{N}^T (\mathbf{o} + t\mathbf{d}) = c \quad \Rightarrow \quad t = \frac{c - \mathbf{N}^T \mathbf{o}}{\mathbf{N}^T \mathbf{d}}$$

- And plug  $t$  back into ray equation:

$$\mathbf{r}(t) = \mathbf{o} + \frac{c - \mathbf{N}^T \mathbf{o}}{\mathbf{N}^T \mathbf{d}} \mathbf{d}$$

# Ray-triangle intersection

- Triangle is in a plane...
- Algorithm:
  - Compute ray-plane intersection
  - Q: What do we do now?

# Barycentric coordinates (as ratio of areas)

Area of triangle formed  
by points: a, b, x

Barycentric coords are *signed* areas:

$$\alpha = A_A/A$$

$$\beta = A_B/A$$

$$\gamma = A_C/A$$

Why must coordinates sum to one?

Why must coordinates be between 0 and 1?

Useful: Heron's formula:

$$A_C = \frac{1}{2}(b - a) \times (x - a)$$

# Ray-triangle intersection

## ■ Algorithm:

- Compute ray-plane intersection
- Compute barycentric coordinates of hit point
- If barycentric coordinates are all positive, point is in triangle

## ■ Many different techniques if you care about efficiency

# Ray-triangle intersection (another way)

- Parameterize triangle with vertices  $\mathbf{p}_0, \mathbf{p}_1, \mathbf{p}_2$  using barycentric coordinates \*

$$f(u, v) = (1 - u - v)\mathbf{p}_0 + u\mathbf{p}_1 + v\mathbf{p}_2$$

- Can think of a triangle as an affine map of the unit triangle

\* I'm writing  $u, v$  instead of beta, gamma to make explicit representation of triangle very clear.

# Another way: ray-triangle intersection

Plug parametric ray equation directly into equation for points on triangle:

$$\mathbf{p}_0 + u(\mathbf{p}_1 - \mathbf{p}_0) + v(\mathbf{p}_2 - \mathbf{p}_0) = \mathbf{o} + t\mathbf{d}$$

Solve for  $u, v, t$ :

$$\underbrace{\begin{bmatrix} \mathbf{p}_1 - \mathbf{p}_0 & \mathbf{p}_2 - \mathbf{p}_0 & -\mathbf{d} \end{bmatrix}}_{\mathbf{M}} \begin{bmatrix} u \\ v \\ t \end{bmatrix} = \mathbf{o} - \mathbf{p}_0$$

$\mathbf{M}^{-1}$  transforms triangle back to unit triangle in  $u, v$  plane, and transforms ray's direction to be orthogonal to plane. It's a point in 2D triangle test now!

# One more query: mesh-mesh intersection

- **GEOMETRY:** How do we know if a mesh intersects itself?
- **ANIMATION:** How do we know if a collision occurred?

# Warm up: point-point intersection

- Q: How do we know if  $p$  intersects  $a$ ?
- A: ...check if they're the same point!

$(p_x, p_y)$   
●

●  $(a_1, a_2)$

# Slightly harder: point-line intersection

- **Q: How do we know if a point intersects a given line?**
- **A: ...plug it into the line equation!**

**p**  
●

$$N^T x = c$$

# Line-line intersection

- Two lines:  $ax=b$  and  $cx=d$
- Q: How do we find the intersection?
- A: See if there is a simultaneous solution

- Leads to linear system: 
$$\begin{bmatrix} a_1 & a_2 \\ c_1 & c_2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} b \\ d \end{bmatrix}$$

# Degenerate line-line intersection?

- **What if lines are almost parallel?**
- **Small change in normal can lead to big change in intersection!**
- **Instability very common, very important with geometric predicates. Demands special care (e.g., analysis of matrix).**

# Triangle-triangle intersection?

- Lots of ways to do it

- Basic idea:

- Q: Any ideas?

- One way: reduce to edge-triangle intersection

- Check if each line passes through plane (ray-triangle)

- Then do interval test

- What if triangle is *moving*?

- Important case for animation

- Can think of triangles as *prisms* in time

- Turns dynamic problem (in  $nD + \text{time}$ ) into purely geometric problem in  $(n+1)$ -dimensions

# Ray-scene intersection

Given a scene defined by a set of  $N$  primitives and a ray  $r$ , find the closest point of intersection of  $r$  with the scene

```
t_closest = inf
for each primitive p in scene:
  t = p.intersect(r)
  if t >= 0 && t < t_closest:
    t_closest = t
```

```
// closest hit is:
// r.o + t_closest * r.d
```

(Assume `p.intersect(r)` returns value of  $t$  corresponding to the point of intersection with ray  $r$ )

**Complexity?**  $O(N)$

*Can we do better? Of course... but you'll have to wait until next class*

**Rendering via ray casting:  
(one common use of ray-scene intersection tests)**

**Rasterization and ray casting are two algorithms for solving the same problem: determining “visibility from a camera”**

# Recall triangle visibility:

**Question 1: what samples does the triangle overlap?  
("coverage")**

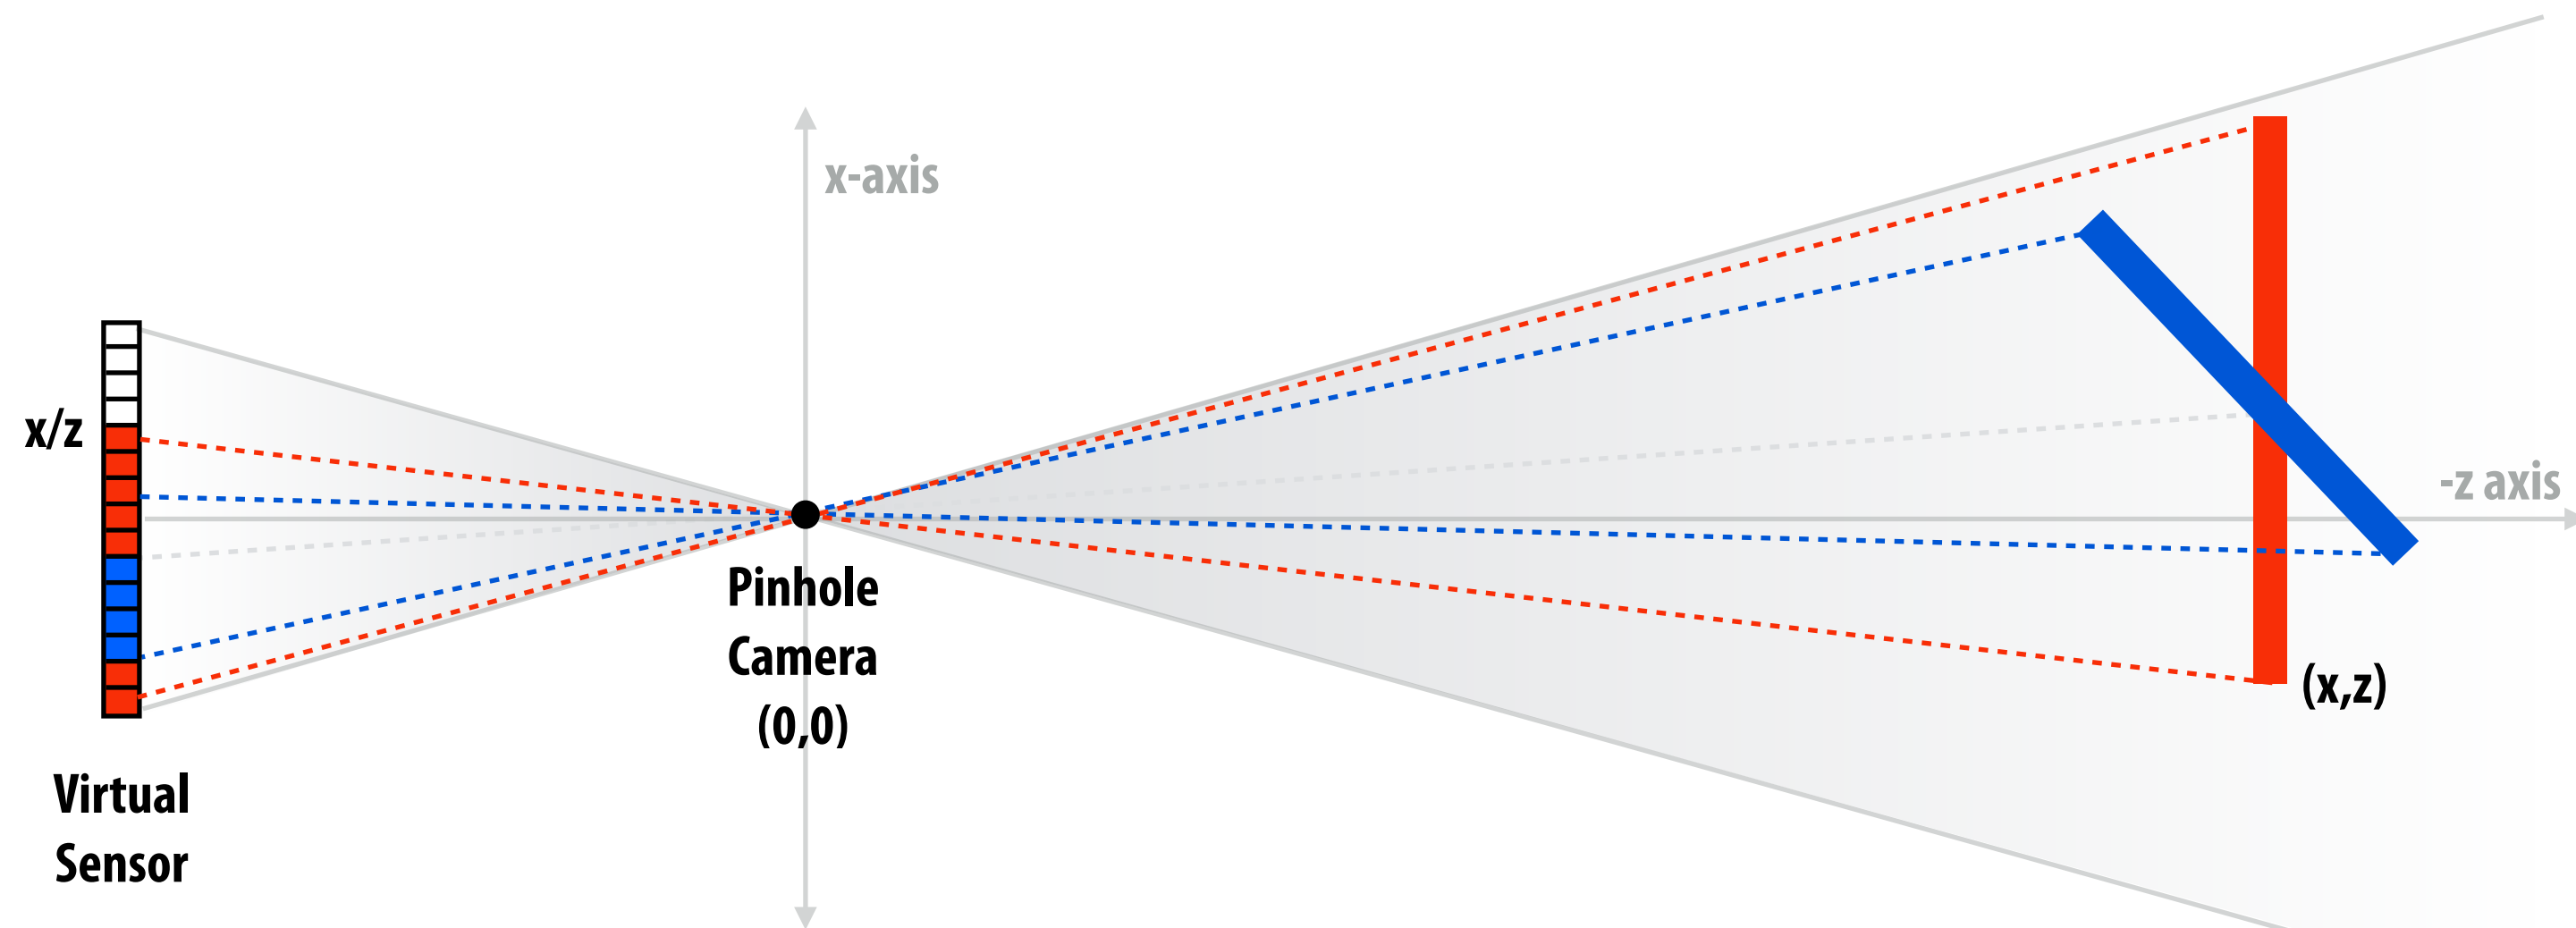

**Sample**

**Question 2: what triangle is closest to the  
camera in each sample? ("occlusion")**

# The visibility problem

- **What scene geometry is visible at each screen sample?**
  - What scene geometry *projects* onto screen sample points? (coverage)
  - Which geometry is visible from the camera at each sample? (occlusion)

# Basic rasterization algorithm

Sample = 2D point

Coverage: 2D triangle/sample tests (does projected triangle cover 2D sample point)

Occlusion: depth buffer

```
initialize z_closest[] to INFINITY // store closest-surface-so-far for all samples
initialize color[] // store scene color for all samples
for each triangle t in scene: // loop 1: over triangles
    t_proj = project_triangle(t)
    for each 2D sample s in frame buffer: // loop 2: over visibility samples
        if (t_proj covers s)
            compute color of triangle at sample
            if (depth of t at s is closer than z_closest[s])
                update z_closest[s] and color[s]
```

***“Given a triangle, find the samples it covers”***

**(finding the samples is relatively easy since they are distributed uniformly on screen)**

**More efficient hierarchical rasterization:**

**For each TILE of image**

**If triangle overlaps tile, check all samples in tile**

# The visibility problem (described differently)

- In terms of casting rays from the camera:
  - Is a scene primitive hit by a ray originating from a point on the virtual sensor and traveling through the aperture of the pinhole camera? (coverage)
  - What primitive is the first hit along that ray? (occlusion)

# Basic ray casting algorithm

Sample = a ray in 3D

Coverage: 3D ray-triangle intersection tests (does ray “hit” triangle)

Occlusion: closest intersection along ray

```
initialize color[] // store scene color for all samples
for each sample s in frame buffer: // loop 1: over visibility samples (rays)
    r = ray from s on sensor through pinhole aperture
    r.min_t = INFINITY // only store closest-so-far for current ray
    r.tri = NULL;
    for each triangle tri in scene: // loop 2: over triangles
        if (intersects(r, tri)) { // 3D ray-triangle intersection test
            if (intersection distance along ray is closer than r.min_t)
                update r.min_t and r.tri = tri;
        }
    color[s] = compute surface color of triangle r.tri at hit point
```

Compared to rasterization approach: just a reordering of the loops!

*“Given a ray, find the closest triangle it hits.”*

# Basic rasterization vs. ray casting

## ■ Rasterization:

- Proceeds in triangle order (for all triangles)
- Store entire depth buffer (requires access to 2D array of fixed size)
- Do not have to store entire scene geometry in memory
  - Naturally supports unbounded size scenes

## ■ Ray casting:

- Proceeds in screen sample order (for all rays)
  - Do not have to store closest depth so far for the entire screen (just the current ray)
  - This is the natural order for rendering transparent surfaces (process surfaces in the order they are encountered along the ray: front-to-back)
- Must store entire scene geometry for fast access

# In other words...

- **Rasterization is an efficient implementation of ray casting where:**
  - **Ray-scene intersection is computed for a batch of rays**
  - **All rays in the batch originate from same origin**
  - **Rays are distributed uniformly in plane of projection**  
(Note: not uniform distribution in angle... angle between rays is smaller away from view direction)

# Generality of ray-scene queries

**What object is visible to the camera?**

**What light sources are visible from a point on a surface (is a surface in shadow?)**

**What reflection is visible on a surface?**

**In contrast, rasterization is a highly-specialized solution for computing visibility for a set of uniformly distributed rays originating from the same point (most often: the camera)**

# Shadows

# How to compute if a surface point is in shadow?

Assume you have an algorithm for ray-scene intersection...

# A simple shadow computation algorithm

- Trace ray from point  $P$  to location  $L_i$  of light source
- If ray hits scene object before reaching light source... then  $P$  is in shadow

# Direct illumination + reflection + transparency

# Global illumination solution

# Direct illumination

• p

# Sixteen-bounce global illumination

• *p*

# Next time: spatial acceleration data structures

- Testing every primitive in scene to find ray-scene intersection is *slow!*
- Consider linearly scanning through a list vs. binary search
  - can apply this same kind of thinking to geometric queries

# Acknowledgements
