Lecture 5:
The Rasterization Pipeline
(and its implementation on GPUs)

Interactive Computer Graphics
Stanford CS248, Winter 2022
What you know how to do (at this point in the course)

**Position objects and the camera in the world**

- Determine the position of objects relative to the camera
- Project objects onto the screen

**Sample triangle coverage**

**Compute triangle attribute values at covered sample points (Color, texture coords, depth)**

**Sample texture maps**
Review
Transformations: from objects to the screen

[WORLD COORDINATES]
original description of objects

[VIEW COORDINATES]
vertex positions now expressed relative to camera; camera is sitting at origin looking down -z direction
(Canonical frame of reference allows for use of canonical projection matrix)

[CLIP COORDINATES]
everything visible to the camera is mapped to unit cube for easy “clipping”
(Also called “normalized device coordinates”)

[WINDOW COORDINATES]
objects now in 2D screen coordinates

primitives are now 2D and can be drawn via rasterization

(view transform)
(projection transform)
(screen transform)

Stanford CS248, Winter 2022
**View frustum**

View frustum is the region of space the camera can see:

- Top/bottom/left/right planes correspond to sides of screen
- Near/far planes correspond to closest/furthest thing we want to draw
Mapping frustum to normalized cube

Before moving to 2D, map corners of view frustum to corners of cube:

View frustum corresponding to pinhole camera (perspective projection transform transforms this volume to normalized cube)

Why do we map frustum to unit cube?
1. Makes *clipping* much easier! (see next slide)
   - Can quickly discard geometry outside range [-1,1]
2. Represent all vertices in normalized cube in fixed point math

* Question: what does the frustum of an orthographic camera look like?
What else do you need to know to render a picture like this?

Surface representation
How to represent complex surfaces?

Occlusion
Determining which surface is visible to the camera at each sample point

Lighting/materials
Describing lights in scene and how materials reflect light.
Course roadmap: what’s coming...

- Introduction
- Drawing a triangle (by sampling)
- Transforms and coordinate spaces
- Perspective projection and texture sampling
- Today: putting it all together: end-to-end triangle rasterization pipeline

Key concepts:
- Sampling (and anti-aliasing)
- Coordinate Spaces and Transforms
- Rasterization and texturing via sampling

Geometry Processing

Materials and Lighting

Drawing Things
Occlusion using the Depth Buffer
Occlusion: which triangle is visible at each covered sample point?

- Opaque Triangles
- 50% transparent triangles
Depth buffer (aka “Z buffer”)

Color buffer:
(stores color per sample… e.g., RGB)

Depth buffer:
(stores depth per sample)

Stores depth of closest surface drawn so far
black = close depth
white = far depth
Depth buffer (a better look)

Color buffer (stores color measurement per sample, eg., RGB value per sample)
Depth buffer (a better look)

Visualization: the darker the pixel, the shorter the distance to the closest object

Corresponding depth buffer after rendering all triangles (stores closest scene depth per sample)
Occlusion using the depth-buffer ("Z-buffer")

For each coverage sample point, the depth-buffer stores depth of closest triangle at this sample point that has been processed by the renderer so far.

Closest triangle at sample point \((x,y)\) is triangle with minimum depth at \((x,y)\)

Initial state of depth buffer before rendering any triangles (all samples store “farthest” distance)

Grayscale value of sample point used to indicate distance
- Black = small distance
- White = large distance
Review from last class

Assume we have a triangle defined by the screen-space 2D position and distance ("depth") from the camera of each vertex.

\[
\begin{align*}
[&p_{0x} & p_{0y}]^T, & d_0 \\
[&p_{1x} & p_{1y}]^T, & d_1 \\
[&p_{2x} & p_{2y}]^T, & d_2
\end{align*}
\]

How do we compute the depth of the triangle at covered sample point \((x, y)\)?

Interpolate it just like any other attribute that varies linearly over the surface of the triangle.
Example: rendering three opaque triangles
Occlusion using the depth-buffer (Z-buffer)

Processing yellow triangle:
depth = 0.5

Grayscale value of sample point used to indicate distance
White = large distance
Black = small distance
Red = samples that pass depth test
Occlusion using the depth-buffer (Z-buffer)

After processing yellow triangle:

Color buffer contents

Depth buffer contents

Grayscale value of sample point used to indicate distance
White = large distance
Black = small distance
Red = samples that pass depth test
Occlusion using the depth-buffer (Z-buffer)

Processing blue triangle:
depth = 0.75

Grayscale value of sample point used to indicate distance:
White = large distance
Black = small distance
Red = samples that pass depth test

Color buffer contents

Depth buffer contents
# Occlusion using the depth-buffer (Z-buffer)

After processing blue triangle:

<table>
<thead>
<tr>
<th>Color buffer contents</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Color buffer contents" /></td>
</tr>
</tbody>
</table>

Grayscale value of sample point used to indicate distance
- White = large distance
- Black = small distance
- Red = samples that pass depth test

<table>
<thead>
<tr>
<th>Depth buffer contents</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Depth buffer contents" /></td>
</tr>
</tbody>
</table>
Occlusion using the depth-buffer (Z-buffer)

Processing red triangle:
depth = 0.25

Grayscale value of sample point used to indicate distance
White = large distance
Black = small distance
Red = samples that pass depth test

Color buffer contents

Depth buffer contents
# Occlusion using the depth-buffer (Z-buffer)

After processing red triangle:

<table>
<thead>
<tr>
<th>Color buffer contents</th>
<th>Depth buffer contents</th>
</tr>
</thead>
<tbody>

</table>
Occlusion using the depth buffer (opaque surfaces)

```cpp
bool pass_depth_test(d1, d2) {
    return d1 < d2;
}

depth_test(tri_d, tri_color, x, y) {
    if (pass_depth_test(tri_d, depth_buffer[x][y]) {
        // if triangle is closest object seen so far at this
        // sample point. Update depth and color buffers.
        depth_buffer[x][y] = tri_d;  // update depth_buffer
        color[x][y] = tri_color;     // update color buffer
    }
}
```
Does depth-buffer algorithm handle interpenetrating surfaces?

Of course!

Occlusion test is based on depth of triangles *at a given sample point*. The relative depth of triangles may be different at different sample points.
Does depth-buffer algorithm handle interpenetrating surfaces?

Of course!

Occlusion test is based on depth of triangles *at a given sample point*. The relative depth of triangles may be different at different sample points.

Now only showing colored samples:
Does depth buffer work with super sampling?

Of course! Occlusion test is per sample, not per pixel!

This example: green triangle occludes yellow triangle
Color buffer contents
Color buffer contents (4 samples per pixel)
Final resampled result

Note anti-aliasing of edge due to filtering of green and yellow samples.
Summary: occlusion using a depth buffer

- Store one depth value per coverage sample (not per pixel!)
- Constant space per sample
  - Implication: constant space for depth buffer
- Constant time occlusion test per covered sample
  - Read-modify write of depth buffer if “pass” depth test
  - Just a depth buffer read if “fail”
- Not specific to triangles: only requires that surface depth can be evaluated at a screen sample point

But what about semi-transparent surfaces?
Compositing
Representing opacity as alpha

Alpha describes the opacity of an object

- Fully opaque surface: $\alpha = 1$
- 50% transparent surface: $\alpha = 0.5$
- Fully transparent surface: $\alpha = 0$

Red triangle with decreasing opacity
Alpha: coverage analogy

- Can think of alpha as describing the opacity of a semi-transparent surface
- Or... as partial coverage by fully opaque object
  - consider a screen door

\( \alpha = 0.5 \)

(Squint at this slide and the scene on the left and the right will appear similar)
Alpha: additional channel of image (rgba)

Alpha describes the opacity of an object
- Fully opaque surface: $\alpha = 1$
- 50% transparent surface: $\alpha = 0.5$
- Fully transparent surface: $\alpha = 0$

$\alpha$ of foreground object
Over operator:

Composite image B with opacity $\alpha_B$ over image A with opacity $\alpha_A$

B over A

A over B

A over B $\neq$ B over A

“Over” is not commutative

Koala over NYC
Over operator: non-premultiplied alpha

Composite image B with opacity $\alpha_B$ over image A with opacity $\alpha_A$

First attempt: (represent colors as 3-vectors, alpha separately)

$$A = \begin{bmatrix} A_r & A_g & A_b \end{bmatrix}^T$$
$$B = \begin{bmatrix} B_r & B_g & B_b \end{bmatrix}^T$$

Composited color:

$$C = \alpha_B B + (1 - \alpha_B)\alpha_A A$$

Composite alpha:

$$\alpha_C = \alpha_B + (1 - \alpha_B)\alpha_A$$

A over B $\neq$ B over A

"Over" is not commutative
Premultiplied alpha representation

- Represent (potentially transparent) color as a 4-vector where RGB values have been premultiplied by alpha

\[ A' = [\alpha_A A_r \quad \alpha_A A_g \quad \alpha_A A_b \quad \alpha_A]^T \]

Example: 50% opaque red
\[ [0.5, 0.0, 0.0, 0.5] \]

Example: 75% opaque magenta
\[ [0.75, 0.0, 0.75, 0.75] \]
Over operator: using premultiplied alpha

Composite image B with opacity $\alpha_B$ over image A with opacity $\alpha_A$

Non-premultiplied alpha representation:

\[
A = \begin{bmatrix} A_r & A_g & A_b \end{bmatrix}^T \\
B = \begin{bmatrix} B_r & B_g & B_b \end{bmatrix}^T \\
C = \alpha_B B + (1 - \alpha_B) \alpha_A A
\]

Composite alpha:

\[
\alpha_C = \alpha_B + (1 - \alpha_B) \alpha_A
\]

Premultiplied alpha representation:

\[
A' = \begin{bmatrix} \alpha_A A_r & \alpha_A A_g & \alpha_A A_b & \alpha_A \end{bmatrix}^T \\
B' = \begin{bmatrix} \alpha_B B_r & \alpha_B B_g & \alpha_B B_b & \alpha_B \end{bmatrix}^T \\
C' = B + (1 - \alpha_B) A
\]

Notice premultiplied alpha composites alpha just like how it composites rgb.

two multiplies, one add (referring to vector ops on colors)

one multiply, one add
Fringing

Poor treatment of color/alpha can yield dark “fringing”:
No fringing
Fringing (…why does this happen?)
A problem with non-premultiplied alpha

- Suppose we upsample an image with an alpha mask, then composite it onto a background.
- How should we compute the interpolated color/alpha values?
- If we interpolate color and alpha separately, then blend using the non-premultiplied “over” operator, here’s what happens:

Notice black “fringe” that occurs because we’re blending, e.g., 50% blue pixels using 50% alpha, rather than, 100% blue pixels with 50% alpha.
Eliminating fringe w/ premultiplied “over”

If we instead use the premultiplied “over” operation, we get the correct alpha:

\[
\text{upsampled color} + (1-\alpha) \times \text{background} = \text{composite image w/ no fringe}
\]
Another problem with non-premultiplied alpha

Consider pre-filtering a texture with an alpha matte

![Leaf images](image)

**Input color**: 
- Red
- Green
- Blue

**Input α**: 
- White

**Filtered color**: 
- Yellow

**Filtered α**: 
- Gray

**Filtered result compositied over white**: 
- Green

Downsampling non-premultiplied alpha image results in 50% opaque brown:

\[
0.25 \times ((0, 1, 0, 1) + (0, 1, 0, 1) + (0, 0, 0, 0) + (0, 0, 0, 0)) = (0, 0.5, 0, 0.5)
\]
Common use of textures with alpha: foliage

[Image credit: SpeedTree Cinema 8]
Another problem: applying “over” repeatedly

Consider composite image $C$ with opacity $\alpha_C$ over $B$ with opacity $\alpha_B$ over image $A$ with opacity $\alpha_A$

$$A = \begin{bmatrix} A_r & A_g & A_b \end{bmatrix}^T$$
$$B = \begin{bmatrix} B_r & B_g & B_b \end{bmatrix}^T$$
$$C = \alpha_B B + (1 - \alpha_B) \alpha_A A$$
$$\alpha_C = \alpha_B + (1 - \alpha_B) \alpha_A$$

Consider first step of compositing 50% red over 50% red:
$$C = \begin{bmatrix} 0.75 & 0 & 0 \end{bmatrix}^T$$
$$\alpha_C = 0.75$$
Wait… this result is the premultiplied color!
So “over” for non-premultiplied alpha takes non-premultiplied colors to premultiplied colors (“over” operation is not closed)

Cannot compose “over” operations on non-premultiplied values:
over($C$, over($B$, $A$))

There is a closed form for non-premultiplied alpha:
$$C = \frac{1}{\alpha_C} (\alpha_B B + (1 - \alpha_B) \alpha_A A)$$
Summary: advantages of premultiplied alpha

- Simple: compositing operation treats all channels (rgb and a) the same
- Closed under composition
- Better representation for filtering textures with alpha channel
- More efficient than non-premultiplied representation: “over” requires fewer math ops
Color buffer update: semi-transparent surfaces

Assume: color buffer values and tri_color are represented with premultiplied alpha

```plaintext
over(c1, c2) {
    return c1 + (1-c1.a) * c2;
}

update_color_buffer(tri_z, tri_color, x, y) {
    // Note: no depth check, no depth buffer update
    color[x][y] = over(tri_color, color[x][y]);
}
```

What is the assumption made by this implementation?

**Triangles must be rendered in back to front order!**

What if triangles are rendered in front to back order?

**Modify code:** 
```
over(color[x][y], tri_color)
```
Putting it all together *

Consider rendering a mixture of opaque and transparent triangles

Step 1: render opaque surfaces using depth-buffered occlusion
   If pass depth test, triangle overwrites value in color buffer at sample

Step 2: disable depth buffer update, render semi-transparent surfaces in back-to-front order.
   If pass depth test, triangle is composited OVER contents of color buffer at sample

* If this seems a little complicated, you will enjoy the simplicity of using ray tracing algorithm for rendering.
More on this later in the course, and in CS348B
Combining opaque and semi-transparent triangles

Assume: color buffer values and tri_color are represented with premultiplied alpha

// phase 1: render opaque surfaces
update_color_buffer(tri_z, tri_color, x, y) {
    if (pass_depth_test(tri_z, zbuffer[x][y])) {
        color[x][y] = tri_color;
        zbuffer[x][y] = tri_z;
    }
}

// phase 2: render semi-transparent surfaces
update_color_buffer(tri_z, tri_color, x, y) {
    if (pass_depth_test(tri_z, zbuffer[x][y])) {
        // Note: no depth buffer update
        color[x][y] = over(tri_color, color[x][y]);
    }
}
End-to-end rasterization pipeline
(“real-time graphics pipeline”)
Command: draw these triangles!

Inputs:

list_of_positions = {
  v0x, v0y, v0z,
  v1x, v1y, v1z,
  v2x, v2y, v2z,
  v3x, v3y, v3z,
  v4x, v4y, v4z,
  v5x, v5y, v5z
};

list_of_texcoords = {
  v0u, v0v,
  v1u, v1v,
  v2u, v2v,
  v3u, v3v,
  v4u, v4v,
  v5u, v5v
};

Object-to-camera-space transform: T

Perspective projection transform: P

Size of output image (W, H)

Use depth test / update depth buffer: YES!
Step 1:
Transform triangle vertices into camera space
(apply modeling and camera transform)
Step 2:

Apply perspective projection transform to transform triangle vertices into normalized coordinate space

Camera-space positions: 3D

Normalized space positions

Note: I'm illustrating normalized 3D space after the homogeneous divide, it is more accurate to think of this volume in 3D-H space as defined by:
(-w, -w, -w, w) and (w, w, w, w)
Step 3: clipping

- Discard triangles that lie complete outside the unit cube (culling)
  - They are off screen, don’t bother processing them further
- Clip triangles that extend beyond the unit cube to the cube
  - Note: clipping may create more triangles
Step 4: transform to screen coordinates

Transform vertex xy positions from normalized coordinates into screen coordinates (based on screen w,h)
Step 5: setup triangle (triangle preprocessing)

Compute triangle edge equations
Compute triangle attribute interpolation equations

\[
\begin{align*}
E_{01}(x, y) & \quad U(x, y) \\
E_{12}(x, y) & \quad V(x, y) \\
E_{20}(x, y) & \quad \frac{1}{w}(x, y) \\
Z(x, y) & 
\end{align*}
\]
Step 6: sample coverage

Evaluate attributes $z, u, v$ at all covered samples
Step 6: compute triangle color at sample point

e.g., sample texture map *

* So far, we’ve only described computing triangle’s color at a point by interpolating per-vertex colors, or by sampling a texture map. Later in the course, we’ll discuss more advanced algorithms for computing its color based on material properties and scene lighting conditions.
Step 7: perform depth test (if enabled)

Also update depth value at covered samples (if necessary)
Step 8: update color buffer (if depth test passed)
Step 9:

- Repeat steps 1-8 for all triangles in the scene!
Real time graphics APIs

- OpenGL
- Microsoft Direct3D
- Apple Metal

- You now know a lot about the algorithms implemented underneath these APIs: drawing 3D triangles (key transformations and rasterization), texture mapping, anti-aliasing via supersampling, etc.

- Internet is full of useful tutorials on how to program using these APIs
OpenGL/Direct3D graphics pipeline *

Structures rendering computation as a series of operations on vertices, primitives, fragments, and screen samples

1. Input: vertices in 3D space
2. Vertices in positioned in normalized coordinate space
3. Triangles positioned on screen
4. Fragments (one fragment per covered sample)

Operations on vertices
- Vertex stream

Operations on primitives (triangles, lines, etc.)
- Primitive stream

Operations on fragments
- Fragment stream

Operations on screen samples
- Shaded fragment stream
- Screen sample operations (depth and color)

Output: image (pixels)

* Several stages of the modern OpenGL pipeline are omitted
OpenGL/Direct3D graphics pipeline *

* Several stages of the modern OpenGL pipeline are omitted

**Pipeline inputs:**
- Input vertex data
- Parameters needed to compute position on vertices in normalized coordinates (e.g., transform matrices)
- Parameters needed to compute color of fragments (e.g., textures)
- “Shader” programs that define behavior of vertex and fragment stages

**Operations on vertices**
- Vertex stream
- Transform matrices

**Operations on primitives (triangles, lines, etc.)**
- Primitive stream
- Textures

**Operations on fragments**
- Fragment stream
- Shaded fragment stream

**Operations on screen samples**
- Screen sample operations (depth and color)
Shader programs

Define behavior of vertex processing and fragment processing stages
Describe operation on a single vertex (or single fragment)

Example GLSL fragment shader program

```glsl
uniform sampler2D myTexture;
uniform vec3 lightDir;
varying vec2 uv;
varying vec3 norm;

void diffuseShader()
{
    vec3 kd;
    kd = texture2d(myTexture, uv);
    kd *= clamp(dot(-lightDir, norm), 0.0, 1.0);
    gl_FragColor = vec4(kd, 1.0);
}
```

Shader function executes once per fragment.

Outputs color of surface at sample point corresponding to fragment.

(this shader performs a texture lookup to obtain the surface's material color at this point, then performs a simple lighting computation)
Texture coordinate visualization

Defines mapping from point on surface to point (uv) in texture domain

Red channel = u, Green channel = v
So uv=(0,0) is black, uv=(1,1) is yellow
Rendered result (after evaluating fragment shader for each pixel)
Goal: render very high complexity 3D scenes

- 100's of thousands to millions of triangles in a scene
- Complex vertex and fragment shader computations
- High resolution screen outputs (2-4 Mpixel + supersampling)
- 30-60 fps
Graphics pipeline implementation: GPUs

Specialized processors for executing graphics pipeline computations

Discrete GPU card
(NVIDIA GeForce Titan X)

Integrated GPU: part of modern Intel CPU chip
GPU: heterogeneous, multi-core processor

Modern GPUs offer ~2-4 TFLOPs of performance for executing vertex and fragment shader programs.

T-OP's of fixed-function compute capability over here.

Take Kayvon's Visual Computing Systems course (CS348V) for more details!
Summary

- Occlusion resolved independently at each screen sample using the depth buffer
- Alpha compositing for semi-transparent surfaces
  - Premultiplied alpha forms simply repeated composition
  - “Over” compositing operations is not commutative: requires triangles to be processed in back-to-front (or front-to-back) order

- Graphics pipeline:
  - Structures rendering computation as a sequence of operations performed on vertices, primitives (e.g., triangles), fragments, and screen samples
  - Behavior of parts of the pipeline is application-defined using shader programs.
  - Pipeline operations implemented by highly, optimized parallel processors and fixed-function hardware (GPUs)
